

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

The long-disputed questions as to the ancient bed of the Amu Daria, or Oxus, appear to have received a final settlement in the publication of the studies of Konshin of St. Petersburg. According to him, the river has never directly emptied into the Caspian; but it is probable that at some period an indirect communication has existed between them through Sari-Kamich Lake and the Uzboi, which drained it. The lake was of much greater area, and its overflow reached the Caspian by the Uzboi: its character was saline or brackish. Were this state of things restored, we should have an immense Turanian sea, composed of a northern basin corresponding to that of the Sea of Aral, and a southern one corresponding to the Sari-Kamich area, connected by a wide but shallow neck of water. Into the former the Sir-Daria would empty, with the Sari-Su and the Chiu; into the latter, the Oxus, the Tedient, and the Murgháb. The overflow of brackish water would find its way by the Uzboi to the Caspian.

Those interested in the question of lakes with two outlets would do well to incite exploration of Frances Lake in the North-west territory. This lake, discovered many years ago by Robert Campbell, now of Winnipeg, was reached by him from the head waters of the Liard River, ascending, according to his account, a small stream actually proceeding from the lake. To his surprise, on the other side he found a communication, during the time of high water, with the head waters of the Pelly River. In 1865 information received from officers of the Hudson-Bay company at Victoria, by those of the International telegraph expedition, was to the effect that the Pelly communication was the chief one, and that a lowering of its bed had turned the drainage permanently north-westward, and the connection with the Liard had become nearly or entirely dry. This has since been indicated on most charts; but, as the lake covers some four hundred and fifty square miles, fuller and confirmatory evidence would be very desirable. The Liard is an affluent of the Mackenzie, and the Pelly of the Yukon River.

THE STATE SURVEY OF NEW YORK.

THE veto of the appropriation for this survey by the late governor of New York caused only a partial suspension of its functions. The survey exists by reason of an organic law creating the commission, and defining its powers. Only by the repeal of this law can the survey be abolished. Its work has been confined to a triangulation so accurately executed as to form a reliable basis for all local surveys and topographical work; but the value of such careful measurements is somewhat difficult for the unscientific man to understand, and the results are not immediately apparent.

To remove all doubts regarding the excellence and economy of the work under their control, the commissioners requested an investigation by the U. S. coast and geodetic survey. After a full examination

of the records of eight years' work, Superintendent Hilgard transmitted them to the state authorities, with his full indorsement.

By this appeal to a most competent authority, the commissioners and director of the New-York state survey have established the fact that the work slowly accomplished with small appropriations since 1876 has been done in the best way and at a small cost. Their report just made to the legislature, having vindicated the work of the past, recommends a radical change in the future policy of the survey. It is urged that New York should be warned by the experience of Massachusetts that a triangulation not immediately followed by a detailed topographical survey gives but little satisfaction to the people. The citizens of a state want reliable maps which they can use, not mere skeleton maps which are only available for surveyors. The board therefore recommends that the legislature enlarge its powers, and increase the appropriations for the state survey, so that topographical surveys may be at once begun in at least three counties, and be carried forward on such a scale as to permit of the economical performance of the work. The cost of the topographical work is estimated at from ten dollars to twenty dollars per square mile, depending upon the character of the country, and the scale of expenditure recommended is forty thousand dollars per annum. For this sum, complete maps of from three to five counties could be made each year, and the maps, by counties, issued within a year after the field-work is done. It is proposed to have the U. S. coast and geodetic survey complete the primary and secondary triangulations, leaving the funds of the state to be used for tertiary triangulation and topographical work.

The experience of the director of the survey, who is by law the engineering member of the state board of health, has proved conclusively the wide-spread need of topographical maps to aid in the sanitary work of the state. The commissioners therefore affirm that there is pressing necessity for topographical maps for sanitary works on water-supplies and drainage; that no survey can meet the wants of the people that does not result in a reliable map sufficiently detailed for ordinary practical and scientific purposes; and that the people have a right to expect that the benefits of the survey will be made immediately available in the form of useful maps.

PROPOSED NEW METHOD OF MEASURING THE DENSITY OF THE EARTH.

THE only known way of measuring the density of the earth is through the 'gravitation constant,' which expresses the attraction exerted by a known mass at a given distance. The bodies whose attractions have been measured are either mountains or portions of the earth, as in the well-known experiments of Maskelyne and Airy; or portable masses of lead, as used by Bailey and others. The difficulty in the way of the former experiments is the necessary uncertainty of the density of those portions of the earth's mass in
